Lecture 4: Power Flow

Prof. Tom Overbye
Dept. of Electrical and Computer Engineering
Texas A&M University
overbye@tamu.edu
Announcements

• Read Chapter 6 from the book
• Homework 1 is due on Thursday Sept. 13
• Adam Birchfield will be giving a special lecture on synthetic grids next time
In the Newton-Raphson power flow we use Newton's method to determine the voltage magnitude and angle at each bus in the power system.

We need to solve the power balance equations

\[
P_i = \sum_{k=1}^{n} V_i V_k (G_{ik} \cos \theta_{ik} + B_{ik} \sin \theta_{ik}) = P_{Gi} - P_{Di}
\]

\[
Q_i = \sum_{k=1}^{n} V_i V_k (G_{ik} \sin \theta_{ik} - B_{ik} \cos \theta_{ik}) = Q_{Gi} - Q_{Di}
\]
Power Flow Jacobian Matrix, cont’d

Jacobian elements are calculated by differentiating each function, $f_i(x)$, with respect to each variable. For example, if $f_i(x)$ is the bus $i$ real power equation

$$f_i(x) = \sum_{k=1}^{n} V_i V_k (G_{ik} \cos \theta_{ik} + B_{ik} \sin \theta_{ik}) - P_{Gi} + P_{Di}$$

$$\frac{\partial f_i(x)}{\partial \theta_i} = \sum_{k=1}^{n} V_i V_k (-G_{ik} \sin \theta_{ik} + B_{ik} \cos \theta_{ik})$$

$$\frac{\partial f_i(x)}{\partial \theta_j} = V_i V_j (G_{ik} \sin \theta_{ik} - B_{ik} \cos \theta_{ik}) \quad (j \neq i)$$
Two Bus Newton-Raphson Example

For the two bus power system shown below, use the Newton-Raphson power flow to determine the voltage magnitude and angle at bus two. Assume that bus one is the slack and $S_{Base} = 100$ MVA.

\[
\begin{align*}
\mathbf{x} &= \begin{bmatrix} \theta_2 \\ V_2 \end{bmatrix} \\
\mathbf{Y}_{bus} &= \begin{bmatrix} -j10 & j10 \\ j10 & -j10 \end{bmatrix}
\end{align*}
\]
Two Bus Example, cont’d

General power balance equations

\[ P_i = \sum_{k=1}^{n} |V_i| |V_k| (G_{ik} \cos \theta_{ik} + B_{ik} \sin \theta_{ik}) = P_{Gi} - P_{Di} \]

\[ Q_i = \sum_{k=1}^{n} |V_i| |V_k| (G_{ik} \sin \theta_{ik} - B_{ik} \cos \theta_{ik}) = Q_{Gi} - Q_{Di} \]

Bus two power balance equations

\[ |V_2| |V_1| (10\sin \theta_2) + 2.0 = 0 \]

\[ |V_2| |V_1| (-10\cos \theta_2) + |V_2|^2 (10) + 1.0 = 0 \]
Two Bus Solved Values

- Once the voltage angle and magnitude at bus 2 are known we can calculate all the other system values, such as the line flows and the generator reactive power.

PowerWorld Case Name: **Bus2Intro**

Note, most PowerWorld cases will be available on course website.
Two Bus Case Low Voltage Solution

This case actually has two solutions! The second "low voltage" is found by using a low initial guess.

Set \( \nu = 0 \), guess \( \mathbf{x}^{(0)} = \begin{bmatrix} 0 \\ 0.25 \end{bmatrix} \)

Calculate

\[
f(\mathbf{x}^{(0)}) = \begin{bmatrix} |V_2|(10\sin \theta_2) + 2.0 \\ |V_2|(-10\cos \theta_2) + |V_2|^2(10) + 1.0 \end{bmatrix} = \begin{bmatrix} 2 \\ -0.875 \end{bmatrix}
\]

\[
\mathbf{J}(\mathbf{x}^{(0)}) = \begin{bmatrix} 10|V_2|\cos \theta_2 & 10\sin \theta_2 \\ 10|V_2|\sin \theta_2 & -10\cos \theta_2 + 20|V_2| \end{bmatrix} = \begin{bmatrix} 2.5 & 0 \\ 0 & -5 \end{bmatrix}
\]
Low Voltage Solution, cont'd

Solve \( x^{(1)} = \begin{bmatrix} 0 \\ 0.25 \end{bmatrix} - \begin{bmatrix} 2.5 & 0 \\ 0 & -5 \end{bmatrix}^{-1} \begin{bmatrix} 2 \\ -0.875 \end{bmatrix} = \begin{bmatrix} -0.8 \\ 0.075 \end{bmatrix} \)

\( f(x^{(2)}) = \begin{bmatrix} 1.462 \\ 0.534 \end{bmatrix} \)
\( x^{(2)} = \begin{bmatrix} -1.42 \\ 0.2336 \end{bmatrix} \)
\( x^{(3)} = \begin{bmatrix} -0.921 \\ 0.220 \end{bmatrix} \)

Low voltage solution
Most commercial software packages have built-in defaults to prevent convergence to low voltage solutions.

- One approach is to automatically change the load model from constant power to constant current or constant impedance when the load bus voltage gets too low.
- In PowerWorld, these defaults can be modified on the Tools, Simulator Options, Advanced Options page; note you also need to disable the “Initialize from Flat Start Values” option.
- The PowerWorld case Bus2_Intro_Low is set solved to the low voltage solution.
- Initial bus voltages can be set using the Bus Information Dialog.
Two Bus Region of Convergence

Slide shows the region of convergence for different initial guesses of bus 2 angle (x-axis) and magnitude (y-axis).

Red region converges to the high voltage solution, while the yellow region converges to the low voltage solution.
Power Flow Fractal Region of Convergence

An Unexpected Low Voltage Solution

The 8/14/03 MISO day ahead model had 65 energized 115,138, or 230 kV buses with voltages below 0.90 pu.

The lowest 138 kV voltage was 0.836 pu; lowest 34.5 kV was 0.621 pu; case contained 42,766 buses; case had been used daily all summer. This was a low voltage solution!
PV Buses

- Since the voltage magnitude at PV buses is fixed there is no need to explicitly include these voltages in $x$ or write the reactive power balance equations
  - the reactive power output of the generator varies to maintain the fixed terminal voltage (within limits)
  - optionally these variations/equations can be included by just writing the explicit voltage constraint for the generator bus

\[ |V_i| - V_i_{setpoint} = 0 \]
Three Bus PV Case Example

For this three bus case we have

\[
x = \begin{bmatrix} \theta_2 \\ \theta_3 \\ V_2 \end{bmatrix} \quad f(x) = \begin{bmatrix} P_2(x) - P_{G2} + P_{D2} \\ P_3(x) - P_{G3} + P_{D3} \\ Q_2(x) + Q_{D2} \end{bmatrix} = 0
\]

\[
\begin{align*}
\text{One} & \quad 170.0 \text{ MW} \\
& \quad 68.2 \text{ MVR}
\end{align*}
\]

\[
\begin{align*}
\text{Two} & \quad 200 \text{ MW} \\
& \quad 100 \text{ MVR}
\end{align*}
\]

\[
\begin{align*}
\text{Three} & \quad 30 \text{ MW} \\
& \quad 63 \text{ MVR}
\end{align*}
\]

\[
\begin{align*}
\text{Line Z = 0.1j} & \quad 0.941 \text{ pu} \\
& \quad -7.469 \text{ Deg}
\end{align*}
\]
Modeling Voltage Dependent Load

So far we've assumed that the load is independent of the bus voltage (i.e., constant power). However, the power flow can be easily extended to include voltage dependence with both the real and reactive load. This is done by making $P_{Di}$ and $Q_{Di}$ a function of $|V_i|:

$$\sum_{k=1}^{n} |V_i| |V_k| (G_{ik} \cos \theta_{ik} + B_{ik} \sin \theta_{ik}) - P_{Gi} + P_{Di}(|V_i|) = 0$$

$$\sum_{k=1}^{n} |V_i| |V_k| (G_{ik} \sin \theta_{ik} - B_{ik} \cos \theta_{ik}) - Q_{Gi} + Q_{Di}(|V_i|) = 0$$
In previous two bus example now assume the load is constant impedance, so

\[ P_2(x) = |V_2|(10\sin \theta_2) + 2.0|V_2|^2 = 0 \]

\[ Q_2(x) = |V_2|(-10\cos \theta_2) + |V_2|^2(10) + 1.0|V_2|^2 = 0 \]

Now calculate the power flow Jacobian

\[ J(x) = \begin{bmatrix}
10|V_2|\cos \theta_2 & 10\sin \theta_2 + 4.0|V_2| \\
10|V_2|\sin \theta_2 & -10\cos \theta_2 + 20|V_2| + 2.0|V_2| 
\end{bmatrix} \]
Voltage Dependent Load, cont'd

Again set \( v = 0 \), guess \( x^{(0)} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \)

Calculate

\[
f(x^{(0)}) = \begin{bmatrix} \left| V_2 \right| (10 \sin \theta_2) + 2.0 \left| V_2 \right|^2 \\ \left| V_2 \right| (-10 \cos \theta_2) + \left| V_2 \right|^2 (10) + 1.0 \left| V_2 \right|^2 \end{bmatrix} = \begin{bmatrix} 2.0 \\ 1.0 \end{bmatrix}
\]

\[
J(x^{(0)}) = \begin{bmatrix} 10 & 4 \\ 0 & 12 \end{bmatrix}
\]

Solve \( x^{(1)} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} - \begin{bmatrix} 10 & 4 \\ 0 & 12 \end{bmatrix}^{-1} \begin{bmatrix} 2.0 \\ 1.0 \end{bmatrix} = \begin{bmatrix} -0.1667 \\ 0.9167 \end{bmatrix} \)
With constant impedance load the MW/Mvar load at bus 2 varies with the square of the bus 2 voltage magnitude. This if the voltage level is less than 1.0, the load is lower than 200/100 MW/Mvar.

PowerWorld Case Name: Bus2_Intro_Z
Generator Reactive Power Limits

- The reactive power output of generators varies to maintain the terminal voltage; on a real generator this is done by the exciter.
- To maintain higher voltages requires more reactive power.
- Generators have reactive power limits, which are dependent upon the generator's MW output.
- These limits must be considered during the power flow solution.
• During power flow once a solution is obtained check to make generator reactive power output is within its limits

• If the reactive power is outside of the limits, fix $Q$ at the max or min value, and resolve treating the generator as a PQ bus
  • this is know as "type-switching"
  • also need to check if a PQ generator can again regulate

• Rule of thumb: to raise system voltage we need to supply more vars
The N-R Power Flow: 5-bus Example

This five bus example is taken from Chapter 6 of Power System Analysis and Design by Glover, Overbye, and Sarma, 6th Edition, 2016

• Goal is to provide an intuitive feel for power system operation
• Emphasis will be on the impact of the transmission system
• Introduce basic power flow concepts through small system examples
Power System Basics

• All power systems have three major components: Generation, Load and Transmission/Distribution.
• Generation: Creates electric power.
• Load: Consumes electric power.
• Transmission/Distribution: Transmits electric power from generation to load.
  • Lines/transformers operating at voltages above 100 kV are usually called the transmission system. The transmission system is usually networked.
  • Lines/transformers operating at voltages below 100 kV are usually called the distribution system (radial).
Large System Example: Texas 2000
Bus Synthetic System

Adam will be talking about synthetic grids next time
Load with green arrows indicating amount of MW flow

Used to control output of generator

MW Losses: 0.28 MW

Direction of green arrow is used to indicate direction of real power (MW) flow; the blue arrows show the reactive power

Note the power balance at each bus

Scheduled Transactions
0.0 MW
Off AGC
Basic Power Control

• Opening a circuit breaker causes the power flow to instantaneously (nearly) change.

• No other way to directly control power flow in a transmission line.

• By changing generation we can indirectly change this flow.

• Power flow in transmission line is limited by heating considerations.

• Losses ($I^2 R$) can heat up the line, causing it to sag.
Modeling Consideration – Change is Not Really Instantaneous!

- The change isn’t really instantaneous because of propagation delays, which are near the speed of light; there also wave reflection issues.
- This is covered in ECEN 667.

Red is the $v_s$ end, green the $v_2$ end.
Transmission Line Limits

- Power flow in transmission line is limited by heating considerations.
- Losses ($I^2 R$) can heat up the line, causing it to sag.
- Each line has a limit; many utilities use winter/summer limits.

Interconnected Operation Balancing Authority (BA) Areas

• North American Eastern and Western grids are divided into balancing authority areas (BA)
  • Often just called an area

• Transmission lines that join two areas are known as tie-lines.

• The net power out of an area is the sum of the flow on its tie-lines.

• The flow out of an area is equal to

  total gen - total load - total losses = tie-flow
US Balancing Authorities

U.S. electric power regions

Interconnections
Eastern
ERCOT
Western

Circles represent the 66 balancing authorities
Area Control Error (ACE)

- The area control error is the difference between the actual flow out of an area, and the scheduled flow
  - ACE also includes a frequency component that we will probably consider later in the semester
- Ideally the ACE should always be zero
- Because the load is constantly changing, each utility (or ISO) must constantly change its generation to “chase” the ACE
- ACE was originally computed by utilities; increasingly it is computed by larger organizations such as ISOs
