ECEN 667 Power System Stability

Lecture 16: Time-Domain Simulation Solutions (Transient Stability)

Prof. Tom Overbye Dept. of Electrical and Computer Engineering Texas A&M University overbye@tamu.edu

Announcements

- Read Chapters 4 and 7
- Homework 5 is due on Tuesday Oct 31

Two Bus Example with Two GENROU Models

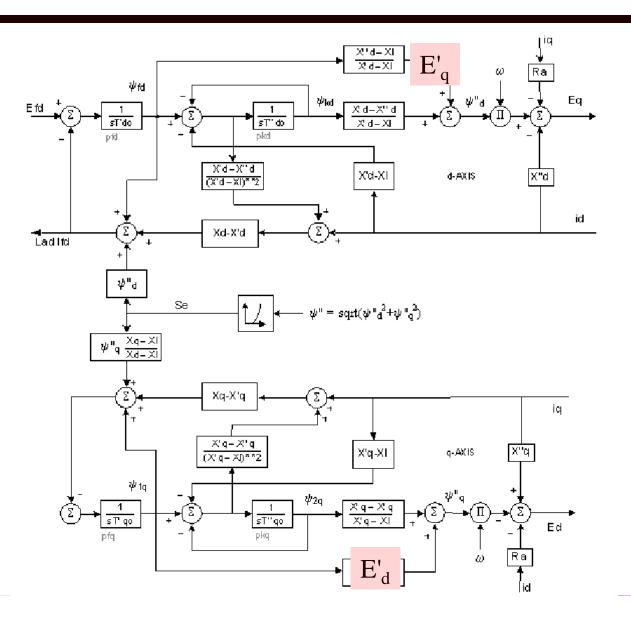

- Use the same system as before, except with we'll model both generators using GENROUs
 - For simplicity we'll make both generators identical except set H₁=3, H₂=6; other values are $X_d=2.1$, $X_q=0.5$, $X'_d=0.2$, $X'_q=0.5$, $X''_q=X''_d=0.18$, $X_1=0.15$, $T'_{do} = 7.0$, $T'_{qo}=0.75$, $T''_{do}=0.035$, $T''_{qo}=0.05$; no saturation
 - With no saturation the value of the δ 's are determined (as per the earlier lectures) by solving

 $|E| \angle \delta = \overline{V} + (R_s + jX_q)\overline{I}$

– Hence for generator 1

 $|E_1| \angle \delta_1 = 1.0946 \angle 11.59^\circ + (j0.5)(1.052 \angle -18.2^\circ) = 1.431 \angle 30.2^\circ$

GENROU Block Diagram

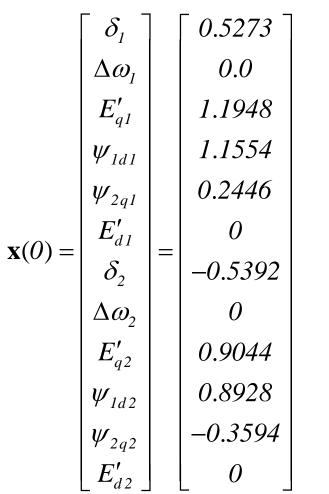

Two Bus Example with Two GENROU Models

• Using the early approach the initial state vector is

Note that this is a salient pole machine with $X'_q = X_q$; hence E'_d will always be zero

The initial currents in the dq reference frame are $I_{d1}=0.7872$, $I_{q1}=0.6988$, $I_{d2}=0.2314$, $I_{q2}=-1.0269$

Initial values of ψ''_{q1} = -0.2236, and ψ''_{d1} = 1.179

Transient Stability Analysis - Case: B2_GENROU_2(

Solving with Euler's

- A M
- We'll again solve with Euler's, except with Δt set now to 0.01 seconds (because now we have a subtransient model with faster dynamics)
 - We'll also clear the fault at t=0.05 seconds
- For the more accurate subtransient models the swing equation is written in terms of the torques

$$\frac{d\delta_i}{dt} = \omega_i - \omega_s = \Delta \omega_i$$

$$\frac{2H_i}{\omega_s} \frac{d\omega_i}{dt} = \frac{2H_i}{\omega_s} \frac{d\Delta \omega_i}{dt} = T_{Mi} - T_{Ei} - D_i \left(\Delta \omega_i\right)$$
with $T_{Ei} = \psi_{d,i}'' i_{qi} - \psi_{q,i}'' i_{di}$

Other equations are solved based upon the block diagram

Norton Equivalent Current Injections

The initial Norton equivalent current injections on the dq base for ulleteach machine are

$$I_{Nd1} + jI_{Nq1} = \frac{\left(-\psi_{q1}'' + j\psi_{d1}''\right)\omega_{1}}{jX_{1}''} = \frac{\left(-0.2236 + j1.179\right)(1.0)}{j0.18}$$

= 6.55 + j1.242
$$I_{ND1} + jI_{NQ1} = 2.222 - j6.286$$

$$I_{Nd2} + jI_{Nq2} = 4.999 + j1.826$$

$$I_{ND2} + jI_{NQ2} = -1 - j5.227$$

Recall the dq values are on the machine's reference frame and the DQ values are on the system reference frame

are on the

frame and

Moving between DQ and dq

• Recall

$$\begin{bmatrix} I_{di} \\ I_{qi} \end{bmatrix} = \begin{bmatrix} \sin \delta & -\cos \delta \\ \cos \delta & \sin \delta \end{bmatrix} \begin{bmatrix} I_{Di} \\ I_{Qi} \end{bmatrix}$$

The currents provide the key coupling between the two reference frames

• And

$$\begin{bmatrix} I_{Di} \\ I_{Qi} \end{bmatrix} = \begin{bmatrix} \sin \delta & \cos \delta \\ -\cos \delta & \sin \delta \end{bmatrix} \begin{bmatrix} I_{di} \\ I_{qi} \end{bmatrix}$$

Bus Admittance Matrix

• The bus admittance matrix is as from before for the classical models, except the diagonal elements are augmented using

$$Y_{i} = \frac{1}{R_{s,i} + jX_{d,i}''}$$
$$Y = Y_{N} + \begin{bmatrix} \frac{1}{j0.18} & 0\\ 0 & \frac{1}{j0.18} \end{bmatrix} = \begin{bmatrix} -j10.101 & j4.545\\ j4.545 & -j10.101 \end{bmatrix}$$

9

Algebraic Solution Verification

• To check the values solve (in the network reference frame)

$$\mathbf{V} = \begin{bmatrix} -j10.101 & j4.545 \\ j4.545 & -j10.101 \end{bmatrix}^{-1} \begin{bmatrix} 2.222 - j6.286 \\ -1 - j5.227 \end{bmatrix}$$
$$= \begin{bmatrix} 1.072 + j0.22 \\ 1.0 \end{bmatrix}$$

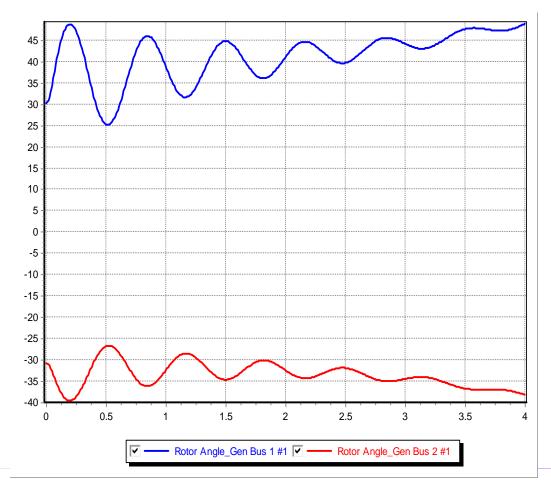

Results

A M

11

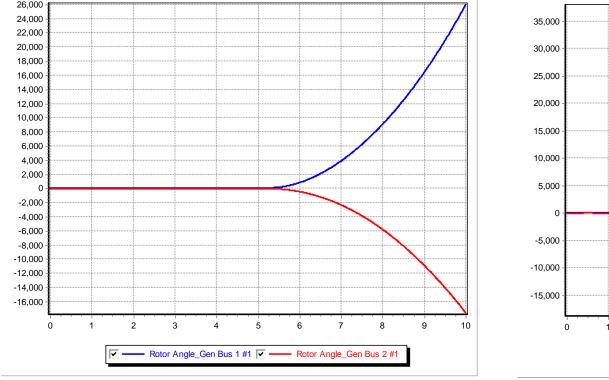

• The below graph shows the results for four seconds of simulation, using Euler's with Δt =0.01 seconds

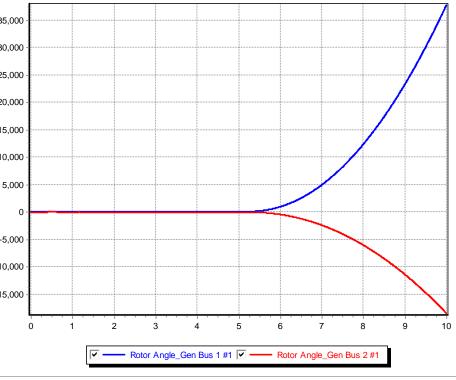

PowerWorld case is **B2_GENROU_2GEN_EULER**

Results for Longer Time

• Simulating out 10 seconds indicates an unstable solution, both using Euler's and RK2 with $\Delta t=0.005$, so it is really unstable!

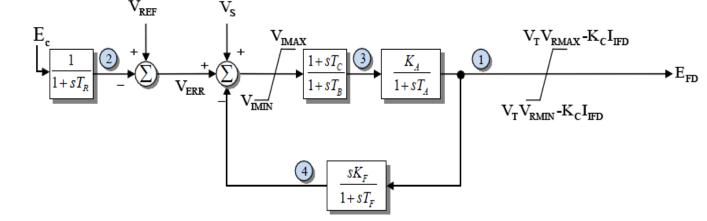

Euler's with $\Delta t=0.01$

RK2 with $\Delta t=0.005$

Adding More Models

- In this situation the case is unstable because we have not modeled exciters
- To each generator add an EXST1 with $T_R=0$, $T_C=T_B=0$, $K_f=0$, $K_A=100$, $T_A=0.1$

- This just adds one differential equation per generator

$$\frac{dE_{FD}}{dt} = \frac{1}{T_A} \left(K_A \left(V_{REF} - \left| V_t \right| \right) - E_{FD} \right)$$

Two Bus, Two Gen With Exciters

• Below are the initial values for this case from PowerWorld

Two Bus Results with Exciters

Â.

- Below graph shows the angles with $\Delta t=0.01$ and a fault clearing at t=0.05 using Euler's
 - With the addition of the exciters case is now stable

Load Models Introduced

- The simplest approach for modeling the loads is to treat them as constant impedances, embedding them in the bus admittance matrix
 Only impact the Y_{bus} diagonals
- The admittances are set based upon their power flow values, scaled by the inverse of the square of the power flow bus voltage

$$\overline{S}_{load,i} = \overline{V}_{i}\overline{I}_{load,i}^{*} = \left|\overline{V}_{i}\right|^{2} \left(G_{load,i} - jB_{load,i}\right)$$
$$G_{load,i} - jB_{load,i} = \frac{\overline{S}_{load,i}}{\left|\overline{V}_{i}\right|^{2}}$$

Note the positive sign comes from the sign convention on $\overline{I}_{load,i}$

In PowerWorld the default load model is specified on **Transient Stability, Options, Power System Model** page

Example 7.4 Case (WSCC 9 Bus)

• PowerWorld Case **Example_7_4** duplicates the example 7.4 case from the book, with the exception of using different generator models

1 Bus1	0.000 - j42.361			-0.000 + j17.361					
2 Bus 2		0.000 - j27.111					-0.000 + j16.000		
3 Bus 3			0.000 - j23.732						-0.000 + j17.065
4 Bus 4	-0.000 + j17.361			3.307 - j39.309	-1.365 + j11.604	-1.942 + j10.511			
5 Bus 5				-1.365 + j11.604	3.814 - j17.843		-1.188 + j5.975		
6 Bus 6				-1.942 + j10.511		4.102 - j16.133			-1.282 + j5.588
7 Bus 7		-0.000 + j16.000			-1.188 + j5.975	-	2.805 - j35.446	-1.617 + j13.698	-
8 Bus 8		_					-1.617 + j13.698	3.741 - j23.642	-1.155 + j9.784
9 Bus 9			-0.000 + j17.065			-1.282 + j5.588		-1.155 + j9.784	2.437 - j32.154

Bus 5 Example: Without the load $Y_{55} = 2.553 - j17.339$ $\overline{S}_{load,5} = 1.25 + j0.5$ and $|\overline{V}_5| = 0.996$ $\mathbf{Y}_{55} = 2.553 - j17.579 + \frac{(1.25 - j0.5)}{|0.996|^2} = 3.813 - j17.843$

Nonlinear Network Equations

- With constant impedance loads the network equations can usually be written with I independent of V, then they can be solved directly (as we've been doing) $V = Y^{-1} I(x)$
- In general this is not the case, with constant power loads one common example. Hence in general a nonlinear solution with Newton's method is used
- We'll generalize the dependence on the algebraic variables, replacing
 V by y since they may include other values beyond just the bus voltages

20

Nonlinear Network Equations

- Just like in the power flow, the complex equations are rewritten, here as a real current and a reactive current $\mathbf{YV} - \mathbf{I}(\mathbf{x}, \mathbf{y}) = \mathbf{0}$ This is a rectangular
- The values for bus i are $g_{Di}(\mathbf{x}, \mathbf{y}) = \sum_{k=1}^{n} \left(G_{ik} V_{Dk} - B_{ik} V_{QK} \right) - I_{NDi} = 0$ $g_{Qi}(\mathbf{x}, \mathbf{y}) = \sum_{k=1}^{n} \left(G_{ik} V_{Qk} + B_{ik} V_{DK} \right) - I_{NQi} = 0$

This is a rectangular formulation; we also could have written the equations in polar form

- For each bus we add two new variables and two new equations
- If an infinite bus is modeled then its variables and equations are omitted since its voltage is fixed

Nonlinear Network Equations

• The network variables and equations are then

$$\mathbf{y} = \begin{bmatrix} V_{D1} \\ V_{Q1} \\ V_{D2} \\ \vdots \\ V_{Dn} \\ V_{Qn} \end{bmatrix} \quad \mathbf{g}(\mathbf{x}, \mathbf{y}) = \begin{bmatrix} \sum_{k=1}^{n} (G_{1k}V_{Dk} - B_{1k}V_{QK}) - I_{ND1}(\mathbf{x}, \mathbf{y}) = 0 \\ \sum_{k=1}^{n} (G_{ik}V_{Qk} + B_{ik}V_{DK}) - I_{ND2}(\mathbf{x}, \mathbf{y}) = 0 \\ \vdots \\ \sum_{k=1}^{n} (G_{2k}V_{Dk} - B_{2k}V_{QK}) - I_{ND2}(\mathbf{x}, \mathbf{y}) = 0 \\ \vdots \\ \sum_{k=1}^{n} (G_{nk}V_{Dk} - B_{nk}V_{QK}) - I_{NDn}(\mathbf{x}, \mathbf{y}) = 0 \\ \sum_{k=1}^{n} (G_{nk}V_{Dk} - B_{nk}V_{QK}) - I_{NDn}(\mathbf{x}, \mathbf{y}) = 0 \end{bmatrix}$$

Nonlinear Network Equation Newton Solution

The network equations are solved using

a similar procedure to that of the

Netwon-Raphson power flow

Set v = 0; make an initial guess of \mathbf{y} , $\mathbf{y}^{(v)}$ While $\|\mathbf{g}(\mathbf{y}^{(v)})\| > \varepsilon$ Do $\mathbf{y}^{(v+1)} = \|\mathbf{y}^{(v)} - \mathbf{J}(\mathbf{y}^{(v)})^{-1}\mathbf{g}(\mathbf{y}^{(v)})$ v = v+1End While

Network Equation Jacobian Matrix

• The most computationally intensive part of the algorithm is determining and factoring the Jacobian matrix, **J**(**y**)

$$\mathbf{J}(\mathbf{y}) = \begin{bmatrix} \frac{\partial g_{D1}(\mathbf{x}, \mathbf{y})}{\partial V_{D1}} & \frac{\partial g_{D1}(\mathbf{x}, \mathbf{y})}{\partial V_{Q1}} & \cdots & \frac{\partial g_{D1}(\mathbf{x}, \mathbf{y})}{\partial V_{Qn}} \\ \frac{\partial g_{Q1}(\mathbf{x}, \mathbf{y})}{\partial V_{D1}} & \frac{\partial g_{Q1}(\mathbf{x}, \mathbf{y})}{\partial V_{Q1}} & \cdots & \frac{\partial g_{Q1}(\mathbf{x}, \mathbf{y})}{\partial V_{Qn}} \\ \vdots & \ddots & \ddots & \vdots \\ \frac{\partial g_{Qn}(\mathbf{x}, \mathbf{y})}{\partial V_{D1}} & \frac{\partial g_{Qn}(\mathbf{x}, \mathbf{y})}{\partial V_{Q1}} & \cdots & \frac{\partial g_{Qn}(\mathbf{x}, \mathbf{y})}{\partial V_{Qn}} \end{bmatrix}$$

Network Jacobian Matrix

- The Jacobian matrix can be stored and computed using a 2 by 2 block ۲ matrix structure
- The portion of the 2 by 2 entries just from the Y_{bus} are \bullet

 $\begin{bmatrix} \frac{\partial \hat{g}_{Di}(\mathbf{x}, \mathbf{y})}{\partial V_{Dj}} & \frac{\partial \hat{g}_{Di}(\mathbf{x}, \mathbf{y})}{\partial V_{Qj}} \\ \frac{\partial \hat{g}_{Qi}(\mathbf{x}, \mathbf{y})}{\partial V_{Dj}} & \frac{\partial \hat{g}_{Qi}(\mathbf{x}, \mathbf{y})}{\partial V_{Qj}} \end{bmatrix} = \begin{bmatrix} G_{ij} & -B_{ij} \\ B_{ij} & G_{ij} \end{bmatrix}$ The "hat" was added to the g functions to indicate it is just the portion from the \mathbf{Y}_{bus}

The major source of the current vector voltage sensitivity comes from • non-constant impedance loads; also dc transmission lines

Example: Constant Current, Constant Power Load

• As an example, assume the load at bus k is represented with a ZIP model

$$P_{Load,k} = P_{BaseLoad,k} \left(P_{z,k} \left| \overline{V}_k^2 \right| + P_{i,k} \left| \overline{V}_k \right| + P_{p,k} \right)$$
$$Q_{Load,k} = Q_{BaseLoad,k} \left(Q_{z,k} \left| \overline{V}_k^2 \right| + Q_{i,k} \left| \overline{V}_k \right| + Q_{p,k} \right)$$

The base load values are set from the power flow

- Constant impedance could be in the \mathbf{Y}_{bus} $\hat{P}_{Load,k} = P_{BaseLoad,k} \left(P_{i,k} \left| \overline{V}_k \right| + P_{p,k} \right) = \left(P_{BL,i,k} \left| \overline{V}_k \right| + P_{BL,p,k} \right)$ $\hat{Q}_{Load,k} = Q_{BaseLoad,k} \left(Q_{i,k} \left| \overline{V}_k \right| + Q_{p,k} \right) = \left(Q_{BL,i,k} \left| \overline{V}_k \right| + Q_{BL,p,k} \right)$
- Usually solved in per unit on network MVA base

ÄМ

Example: Constant Current, Constant Power Load

• The current is then

$$\begin{split} \overline{I}_{Load,k} &= I_{D,Load,k} + jI_{Q,Load,k} = \left(\frac{\hat{P}_{Load,k} + j\hat{Q}_{Load,k}}{\overline{V}_{k}}\right)^{*} \\ &= \left(\frac{\left(P_{BL,i,k}\sqrt{V_{DK}^{2} + V_{QK}^{2}} + P_{BL,p,k}\right) - j\left(Q_{BL,i,k}\sqrt{V_{DK}^{2} + V_{QK}^{2}} + Q_{BL,p,k}\right)}{V_{Dk} - jV_{Qk}}\right) \end{split}$$

• Multiply the numerator and denominator by $V_{DK}+jV_{QK}$ to write as the real current and the reactive current

Example: Constant Current, Constant Power Load

$$\begin{split} I_{D,Load,k} &= \frac{V_{Dk}P_{BL,p,k} + V_{QK}Q_{BL,p,k}}{V_{DK}^2 + V_{QK}^2} + \frac{V_{Dk}P_{BL,i,k} + V_{QK}Q_{BL,i,k}}{\sqrt{V_{DK}^2 + V_{QK}^2}} \\ I_{Q,Load,k} &= \frac{V_{Qk}P_{BL,p,k} - V_{DK}Q_{BL,p,k}}{V_{DK}^2 + V_{QK}^2} + \frac{V_{Qk}P_{BL,i,k} - V_{DK}Q_{BL,i,k}}{\sqrt{V_{DK}^2 + V_{QK}^2}} \end{split}$$

- The Jacobian entries are then found by differentiating with respect to V_{DK} and V_{QK}
 - Only affect the 2 by 2 block diagonal values
- Usually constant current and constant power models are replaced by a constant impedance model if the voltage goes too low, like during a fault

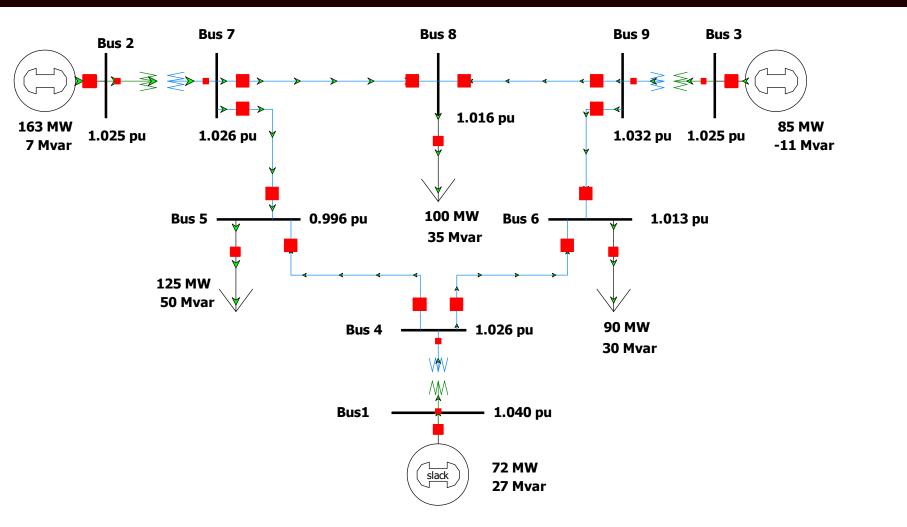

Example: 7.4 ZIP Case

- Example 7.4 is modified so the loads are represented by a model with 30% constant power, 30% constant current and 40% constant impedance
 - In PowerWorld load models can be entered in a number of different ways; a tedious but simple approach is to specify a model for each individual load
 - Right click on the load symbol to display the Load Options dialog, select Stability, and select WSCC to enter a ZIP model, in which p1&q1 are the normalized about of constant impedance load, p2&q2 the amount of constant current load, and p3&q3 the amount of constant power load

Case is **Example_7_4_ZIP**

Example 7.4 ZIP One-line

Example 7.4 ZIP Bus 8 Load Values

• As an example the values for bus 8 are given (per unit, 100 MVA base)

$$1.00 = P_{BaseLoad,8} \left(0.4 \times 1.016^2 + 0.3 \times 1.016 + 0.3 \right)$$

 $\rightarrow P_{BaseLoad,8} = 0.983$

$$0.35 = Q_{BaseLoad,8} \left(0.4 \times 1.016^2 + 0.3 \times 1.016 + 0.3 \right)$$

$$\rightarrow Q_{BaseLoad,8} = 0.344$$

$$I_{D,Load,8} + jI_{Q,Load,8} = \left(\frac{1+j0.35}{1.0158+j0.0129}\right)^* = 0.9887 - j0.332$$

Example: 7.4 ZIP Case Jacobian

• For this case the 2 by 2 block between buses 8 and 7 is

 $\begin{bmatrix} -1.155 & 9.784 \\ -9.784 & -1.155 \end{bmatrix}$

This is referencing slide 29

- And between 8 and 9 is $\begin{bmatrix} -1.617 & 13.698 \\ -13.698 & -1.617 \end{bmatrix}$ These entries are easily checked with the \mathbf{Y}_{bus}
- The 2 by 2 block for the bus 8 diagonal is

 $\begin{bmatrix} 2.876 & -23.352 \\ 23.632 & 3.745 \end{bmatrix}$

The check here is left for the student

Additional Comments

- AM
- When coding Jacobian values, a good way to check that the entries are correct is to make sure that for a small perturbation about the solution the Newton's method has quadratic convergence
- When running the simulation the Jacobian is actually seldom rebuilt and refactored
 - If the Jacobian is not too bad it will still converge
- To converge Newton's method needs a good initial guess, which is usually the last time step solution
 - Convergence can be an issue following large system disturbances, such as a fault

Explicit Method Long-Term Solutions

A M

- The explicit method can be used for long-term solutions
 - For example in PowerWorld DS we've done solutions of large systems for many hours
- Numerical errors do not tend to build-up because of the need to satisfy the algebraic equations
- However, sometimes models have default parameter values that cause unexpected behavior when run over longer periods of time (such as default trips after 99 seconds below 0.1 Hz).
- Some models have slow unstable modes

Simultaneous Implicit

- The other major solution approach is the simultaneous implicit in which the algebraic and differential equations are solved simultaneously
- This method has the advantage of being numerically stable

35

Simultaneous Implicit

- Recalling an initial lecture, we covered two common implicit integration approaches for solving $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$
 - Backward Euler $\mathbf{x}(t + \Delta t) = \mathbf{x}(t) + \Delta t \mathbf{f} (\mathbf{x}(t + \Delta t))$

For a linear system we have

– Trapezoidal

 $\mathbf{x}(t + \Delta t) = \left[I - \Delta t \mathbf{A}\right]^{-1} \mathbf{x}(t)$ $\mathbf{x}(t + \Delta t) = \mathbf{x}(t) + \frac{\Delta t}{2} \left[\mathbf{f}\left(\mathbf{x}(t)\right) + \mathbf{f}\left(\mathbf{x}(t + \Delta t)\right)\right]$

For a linear system we have

$$\mathbf{x}(t + \Delta t) = \left[I - \Delta t \mathbf{A}\right]^{-1} \left[I + \frac{\Delta t}{2} \mathbf{A}\right] \mathbf{x}(t)$$

• We'll just consider trapezoidal, but for nonlinear cases

Nonlinear Trapezoidal

• We can use Newton's method to solve $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ with the trapezoidal

$$-\mathbf{x}(t+\Delta t) + \mathbf{x}(t) + \frac{\Delta t}{2} \left(\mathbf{f} \left(\mathbf{x}(t+\Delta t) \right) + \mathbf{f} \left(\mathbf{x}(t) \right) \right) = \mathbf{0}$$

- We are solving for $\mathbf{x}(t+\Delta t)$; $\mathbf{x}(t)$ is known
- The Jacobian matrix is

J(

$$\mathbf{x}(t+\Delta t) = \frac{\Delta t}{2} \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \dots & \frac{\partial f_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1} & \dots & \frac{\partial f_1}{\partial x_n} \end{bmatrix} - \mathbf{I}$$

The $-\mathbf{I}$ comes from differentiating $-\mathbf{x}(t+\Delta t)$

Right now we are just considering the differential equations; we'll introduce the algebraic equations shortly

Nonlinear Trapezoidal using Newton's Method

A M

- The full solution would be at each time step
 - Set the initial guess for $\mathbf{x}(t+\Delta t)$ as $\mathbf{x}(t)$, and initialize the iteration counter $\mathbf{k} = 0$
 - Determine the mismatch at each iteration k as

$$\mathbf{h}\left(\mathbf{x}(t+\Delta t)^{(k)}\right)\Box - \mathbf{x}(t+\Delta t)^{(k)} + \mathbf{x}(t) + \frac{\Delta t}{2}\left(\mathbf{f}\left(\mathbf{x}(t+\Delta t)^{(k)}\right) + \mathbf{f}\left(\mathbf{x}(t)\right)\right)$$

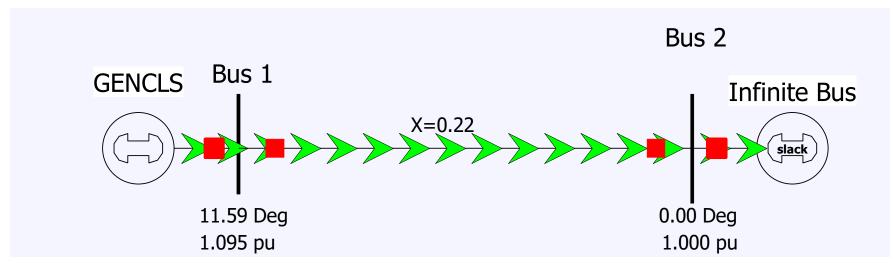

– Determine the Jacobian matrix

- Solve
$$\mathbf{x}(t + \Delta t)^{(k+1)} = \mathbf{x}(t + \Delta t)^{(k)} - \left[\mathbf{J}(\mathbf{x}(t + \Delta t)^{(k)}\right]^{-1} \mathbf{h}\left(\mathbf{x}(t + \Delta t)^{(k)}\right)$$

– Iterate until done

Infinite Bus GENCLS Example

• Use the previous two bus system with gen 4 again modeled with a classical model with $X_d'=0.3$, H=3 and D=0

In this example $X_{th} = (0.22 + 0.3)$, with the internal voltage $\overline{E'}_1 = 1.281 \angle 23.95^\circ$ giving $E'_1 = 1.281 \text{ and } \delta_1 = 23.95^\circ$

- Assume a solid three phase fault is applied at the bus 1 generator terminal, reducing P_{E1} to zero during the fault, and then the fault is self-cleared at time T^{clear} resulting in the post-fault system being identical to the pre-fault system
 - During the fault-on time the equations reduce to

$$\frac{d\delta_{I}}{dt} = \Delta \omega_{I,pu} \omega_{s}$$
$$\frac{d\Delta \omega_{I,pu}}{dt} = \frac{1}{2 \times 3} (1 - 0)$$

That is, with a solid fault on the terminal of the generator, during the fault $P_{E1} = 0$

• The initial conditions are

$$\mathbf{x}(0) = \begin{bmatrix} \delta(0) \\ \omega_{pu}(0) \end{bmatrix} = \begin{bmatrix} 0.418 \\ 0 \end{bmatrix}$$

- Let $\Delta t = 0.02$ seconds
- During the fault the Jacobian is

$$\mathbf{J}\left(\mathbf{x}(t+\Delta t)\right) = \frac{0.02}{2} \begin{bmatrix} 0 & \omega_s \\ 0 & 0 \end{bmatrix} - \mathbf{I} = \begin{bmatrix} -1 & 3.77 \\ 0 & -1 \end{bmatrix}$$

• Set the initial guess for $\mathbf{x}(0.02)$ as $\mathbf{x}(0)$, and

$$\mathbf{f}\left(\mathbf{x}(0)\right) = \begin{bmatrix} 0\\ 0.1667 \end{bmatrix}$$

• Then calculate the initial mismatch

$$\mathbf{h}\left(\mathbf{x}(0.02)^{(0)}\right)\square - \mathbf{x}(0.02)^{(0)} + \mathbf{x}(0) + \frac{0.02}{2}\left(\mathbf{f}\left(\mathbf{x}(0.02)^{(0)}\right) + \mathbf{f}\left(\mathbf{x}(0)\right)\right)$$

• With $\mathbf{x}(0.02)^{(0)} = \mathbf{x}(0)$ this becomes

$$\mathbf{h}\left(\mathbf{x}(0.02)^{(0)}\right) = -\begin{bmatrix} 0.418\\0 \end{bmatrix} + \begin{bmatrix} 0.418\\0 \end{bmatrix} + \frac{0.02}{2} \left(\begin{bmatrix} 0\\0.167 \end{bmatrix} + \begin{bmatrix} 0\\0.167 \end{bmatrix} \right) = \begin{bmatrix} 0\\0.00334 \end{bmatrix}$$

• Then
$$\mathbf{x}(0.02)^{(1)} = \begin{bmatrix} 0.418 \\ 0 \end{bmatrix} - \begin{bmatrix} -1 & 3.77 \\ 0 & -1 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 0.00334 \end{bmatrix} = \begin{bmatrix} 0.4306 \\ 0.00334 \end{bmatrix}$$

• Repeating for the next iteration

$$\mathbf{f}\left(\mathbf{x}(0.02)^{(1)}\right) = \begin{bmatrix} 1.259\\ 0.1667 \end{bmatrix}$$
$$\mathbf{h}\left(\mathbf{x}(0.02)^{(1)}\right) = -\begin{bmatrix} 0.4306\\ 0.00334 \end{bmatrix} + \begin{bmatrix} 0.418\\ 0 \end{bmatrix} + \frac{0.02}{2}\left(\begin{bmatrix} 1.259\\ 0.167 \end{bmatrix} + \begin{bmatrix} 0\\ 0.167 \end{bmatrix}\right)$$
$$= \begin{bmatrix} 0.0\\ 0.0 \end{bmatrix}$$

• Hence we have converged with $\mathbf{x}(0.02) = \begin{bmatrix} 0.4306 \\ 0.00334 \end{bmatrix}$

- Iteration continues until $t = T^{clear}$, assumed to be 0.1 seconds in this example $\mathbf{x}(0.10) = \begin{bmatrix} 0.7321 \\ 0.0167 \end{bmatrix}$
- At this point, when the fault is self-cleared, the equations change, requiring a re-evaluation of $f(\mathbf{x}(T^{clear}))$

$$\frac{d\delta}{dt} = \Delta \omega_{pu} \omega_s$$

$$\frac{d\Delta \omega_{pu}}{dt} = \frac{1}{6} \left(1 - \frac{1.281}{0.52} \sin \delta \right) \qquad \mathbf{f} \left(\mathbf{x} \left(0.1^+ \right) \right) = \begin{bmatrix} 6.30 \\ -0.1078 \end{bmatrix}$$

• With the change in f(x) the Jacobian also changes

$$\mathbf{J}\left(\mathbf{x}(0.12^{(0)})\right) = \frac{0.02}{2} \begin{bmatrix} 0 & \omega_s \\ -0.305 & 0 \end{bmatrix} - \mathbf{I} = \begin{bmatrix} -1 & 3.77 \\ -0.00305 & -1 \end{bmatrix}$$

• Iteration for **x**(0.12) is as before, except using the new function and the new Jacobian

This also converges quickly, with one or two iterations

$$\mathbf{h} \left(\mathbf{x}(0.12)^{(0)} \right) \Box - \mathbf{x}(0.12)^{(0)} + \mathbf{x}(0.01) + \frac{0.02}{2} \left(\mathbf{f} \left(\mathbf{x}(0.12)^{(0)} \right) + \mathbf{f} \left(\mathbf{x}(0.10^+) \right) \right)$$
$$\mathbf{x}(0.12)^{(1)} = \begin{bmatrix} 0.7321 \\ 0.0167 \end{bmatrix} - \begin{bmatrix} -1 & 3.77 \\ -0.00305 & -1 \end{bmatrix}^{-1} \begin{bmatrix} 0.1257 \\ -0.00216 \end{bmatrix} = \begin{bmatrix} 0.848 \\ 0.0142 \end{bmatrix}$$

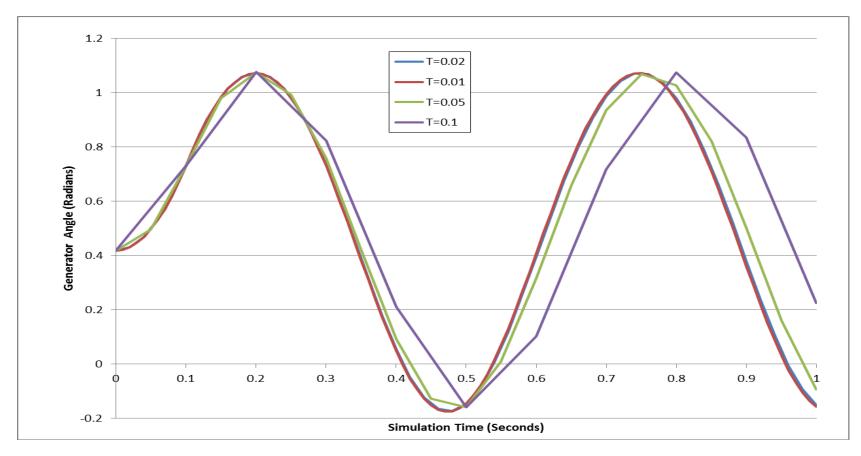

Computational Considerations

- As presented for a large system most of the computation is associated with updating and factoring the Jacobian. But the Jacobian actually changes little and hence seldom needs to be rebuilt/factored
- Rather than using $\mathbf{x}(t)$ as the initial guess for $\mathbf{x}(t+\Delta t)$, prediction can be used when previous values are available

$$\mathbf{x}(t + \Delta t)^{(0)} = \mathbf{x}(t) + (\mathbf{x}(t) - \mathbf{x}(t - \Delta t))$$

Two Bus System Results

• The below graph shows the generator angle for varying values of Δt ; recall the implicit method is numerically stable

46

Adding the Algebraic Constraints

- A M
- Since the classical model can be formulated with all the values on the network reference frame, initially we just need to add the network equations
- We'll again formulate the network equations using the form

I(x,y) = YV or YV - I(x,y) = 0

• As before the complex equations will be expressed using two real equations, with voltages and currents expressed in rectangular coordinates

Adding the Algebraic Constraints

• The network equations are as before

$$\mathbf{y} = \begin{bmatrix} V_{D1} \\ V_{Q1} \\ V_{D2} \\ \vdots \\ V_{Dn} \\ V_{Qn} \end{bmatrix} \quad \mathbf{g}(\mathbf{x}, \mathbf{y}) = \begin{bmatrix} \sum_{k=1}^{n} (G_{1k}V_{Dk} - B_{1k}V_{QK}) - I_{ND1}(\mathbf{x}, \mathbf{y}) = 0 \\ \sum_{k=1}^{n} (G_{ik}V_{Qk} + B_{ik}V_{DK}) - I_{ND2}(\mathbf{x}, \mathbf{y}) = 0 \\ \vdots \\ \sum_{k=1}^{n} (G_{2k}V_{Dk} - B_{2k}V_{QK}) - I_{ND2}(\mathbf{x}, \mathbf{y}) = 0 \\ \vdots \\ \sum_{k=1}^{n} (G_{nk}V_{Dk} - B_{nk}V_{QK}) - I_{NDn}(\mathbf{x}, \mathbf{y}) = 0 \\ \sum_{k=1}^{n} (G_{nk}V_{Qk} + B_{nk}V_{DK}) - I_{NQn}(\mathbf{x}, \mathbf{y}) = 0 \end{bmatrix}$$

Coupling of x and y with the Classical Model

- In the simultaneous implicit method **x** and **y** are determined simultaneously; hence in the Jacobian we need to determine the
- dependence of the network equations on \mathbf{x} , and the state equations on \mathbf{y}
- With the classical model the Norton current depends on **x** as

$$\begin{split} \overline{I}_{Ni} &= \frac{E_i' \angle \delta_i}{R_{s,i} + jX_{d,i}'}, \quad G_i + jB_i = \frac{1}{R_{s,i} + jX_{d,i}'} \\ \overline{I}_{Ni} &= I_{DNi} + jI_{QNi} = E_i' (\cos \delta_i + j \sin \delta_i) (G_i + jB_i) \\ E_{Di} + jE_{Qi} &= E_i' (\cos \delta_i + j \sin \delta_i) \\ I_{DNi} &= E_{Di}G_i - E_{Qi}B_i \\ I_{QNi} &= E_{Di}B_i + E_{Qi}G_i \end{split}$$
Recall with the classical model E_i ' is constant

Coupling of x and y with the Classical Model

• In the state equations the coupling with **y** is recognized by noting

$$P_{Ei} = E_{Di}I_{Di} + E_{Qi}I_{Qi}$$

$$I_{Di} + jI_{Qi} = \left(\left(E_{Di} - V_{Di}\right) + j\left(E_{Qi} - V_{Qi}\right)\right)\left(G_{i} + jB_{i}\right)$$

$$I_{Di} = \left(E_{Di} - V_{Di}\right)G_{i} - \left(E_{Qi} - V_{Qi}\right)B_{i}$$
These are the algebraic equations
$$I_{Qi} = \left(E_{Di} - V_{Di}\right)B_{i} + \left(E_{Qi} - V_{Qi}\right)G_{i}$$

$$P_{Ei} = E_{Di}\left(\left(E_{Di} - V_{Di}\right)G_{i} - \left(E_{Qi} - V_{Qi}\right)B_{i}\right) + E_{Qi}\left(\left(E_{Di} - V_{Di}\right)B_{i} + \left(E_{Qi} - V_{Qi}\right)G_{i}\right)$$

$$P_{Ei} = \left(E_{Di}^{2} - E_{Di}V_{Di}\right)G_{i} + \left(E_{Qi}^{2} - E_{Qi}V_{Qi}\right)G_{i} + \left(E_{Di}V_{Qi} - E_{Qi}V_{Di}\right)B_{i}$$

Hence we have P_{Ei} written in terms of the voltages (y)

Variables and Mismatch Equations

- A M
- In solving the Newton algorithm the variables now include **x** and **y** (recalling that here **y** is just the vector of the real and imaginary bus voltages
- The mismatch equations now include the state integration equations

$$\mathbf{h}\left(\mathbf{x}(t+\Delta t)^{(k)}\right) = -\mathbf{x}(t+\Delta t)^{(k)} + \mathbf{x}(t) + \frac{\Delta t}{2}\left(\mathbf{f}\left(\mathbf{x}(t+\Delta t)^{(k)}, \mathbf{y}(t+\Delta t)^{(k)}\right) + \mathbf{f}\left(\mathbf{x}(t), \mathbf{y}(t)\right)\right)$$

• And the algebraic equations

$$\mathbf{g}(\mathbf{x}(t+\Delta t)^{(k)},\mathbf{y}(t+\Delta t)^{(k)})$$

Jacobian Matrix

- Since the $\mathbf{h}(\mathbf{x}, \mathbf{y})$ and $\mathbf{g}(\mathbf{x}, \mathbf{y})$ are coupled, the Jacobian is $J\left(\mathbf{x}(t + \Delta t)^{(k)}, \mathbf{y}(t + \Delta t)^{(k)}\right)$ $= \begin{bmatrix} \frac{\partial \mathbf{h}\left(\mathbf{x}(t + \Delta t)^{(k)}, \mathbf{y}(t + \Delta t)^{(k)}\right)}{\partial \mathbf{x}} & \frac{\partial \mathbf{h}\left(\mathbf{x}(t + \Delta t)^{(k)}, \mathbf{y}(t + \Delta t)^{(k)}\right)}{\partial \mathbf{y}} \\ \frac{\partial \mathbf{g}\left(\mathbf{x}(t + \Delta t)^{(k)}, \mathbf{y}(t + \Delta t)^{(k)}\right)}{\partial \mathbf{x}} & \frac{\partial \mathbf{g}\left(\mathbf{x}(t + \Delta t)^{(k)}, \mathbf{y}(t + \Delta t)^{(k)}\right)}{\partial \mathbf{y}} \end{bmatrix}$
 - With the classical model the coupling is the Norton current at bus i depends on δ_i (i.e., **x**) and the electrical power (P_{Ei}) in the swing equation depends on V_{Di} and V_{Qi} (i.e., **y**)

Jacobian Matrix Entries

- The dependence of the Norton current injections on δ is
 - $I_{DNi} = E'_{i} \cos \delta_{i} G_{i} E'_{i} \sin \delta_{i} B_{i}$ $I_{QNi} = E'_{i} \cos \delta_{i} B_{i} + E'_{i} \sin \delta_{i} G_{i}$ $\frac{\partial I_{DNi}}{\partial \delta_{i}} = -E'_{i} \sin \delta_{i} G_{i} E'_{i} \cos \delta_{i} B_{i}$ $\frac{\partial I_{QNi}}{\partial \delta_{i}} = -E'_{i} \sin \delta_{i} B_{i} + E'_{i} \cos \delta_{i} G_{i}$
 - In the Jacobian the sign is flipped because we defined
 - $\mathbf{g}(\mathbf{x},\mathbf{y}) = \mathbf{Y}\mathbf{V} \mathbf{I}(\mathbf{x},\mathbf{y})$

Jacobian Matrix Entries

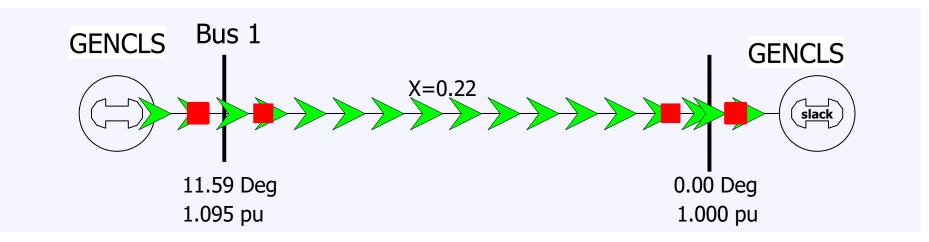

• The dependence of the swing equation on the generator terminal voltage is

$$\begin{split} \dot{\delta_i} &= \Delta \omega_{i,pu} \omega_s \\ \Delta \dot{\omega}_{i,pu} &= \frac{1}{2H_i} \Big(P_{Mi} - P_{Ei} - D_i \left(\Delta \omega_{i,pu} \right) \Big) \\ \mathbf{P}_{Ei} &= \Big(E_{Di}^2 - E_{Di} V_{Di} \Big) G_i + \Big(E_{Qi}^2 - E_{Qi} V_{Qi} \Big) G_i + \Big(E_{Di} V_{Qi} - E_{Qi} V_{Di} \Big) B_i \\ \frac{\partial \Delta \dot{\omega}_{i,pu}}{\partial V_{Di}} &= \frac{1}{2H_i} \Big(E_{Di} G_i + E_{Qi} B_i \Big) \\ \frac{\partial \Delta \dot{\omega}_{i,pu}}{\partial V_{Qi}} &= \frac{1}{2H_i} \Big(E_{Qi} G_i - E_{Di} B_i \Big) \end{split}$$

Ā M

Two Bus, Two Gen GENCLS Example

- We'll reconsider the two bus, two generator case from the previous lecture ; fault at Bus 1, cleared after 0.06 seconds
- Initial conditions and \mathbf{Y}_{bus} are as covered in Lecture 16

PowerWorld Case B2_CLS_2Gen

Two Bus, Two Gen GENCLS Example

• Initial terminal voltages are

$$\begin{split} V_{D1} + jV_{Q1} &= 1.0726 + j0.22, \quad V_{D2} + jV_{Q2} = 1.0\\ \overline{E}_1 &= 1.281 \angle 23.95^\circ, \quad \overline{E}_2 = 0.955 \angle -12.08\\ \overline{I}_{N1} &= \frac{1.1709 + j0.52}{j0.3} = 1.733 - j3.903\\ \overline{I}_{N2} &= \frac{0.9343 - j0.2}{j0.2} = -1 - j4.6714\\ \mathbf{Y} &= \mathbf{Y}_N + \begin{bmatrix} \frac{1}{j0.333} & 0\\ 0 & \frac{1}{j0.2} \end{bmatrix} = \begin{bmatrix} -j7.879 & j4.545\\ j4.545 & -j9.545 \end{bmatrix} \end{split}$$

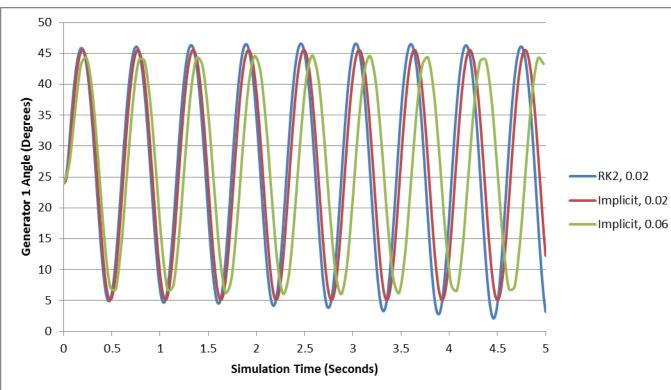

Two Bus, Two Gen Initial Jacobian

Γ	$\delta_{_{I}}$	$\Delta \omega_l$	$\delta_{_2}$	$\Delta \omega_2$	V_{D1}	V_{Q1}	V_{D2}	V_{Q2}
$\dot{\delta_1}$	-1	3.77	0	0	0	0	0	0
$\Delta \dot{\omega}_{I}$	-0.0076	-1	0	0	-0.0029	0.0065	0	0
$\dot{\delta_2}$	0	0	-1	3.77	0	0	0	0
$\Delta \dot{\omega}_2$	0	0	-0.0039	-1	0	0	0.0008	0.0039
I_{D1}	-3.90	0	0	0	0	7.879	0	-4.545
I_{Q1}	-1.73	0	0	0	-7.879	0	4.545	0
I_{D2}	0	0	-4.67	0	0	-4.545	0	9.545
I_{Q2}	0	0	1.00	0	4.545	0	-9.545	0

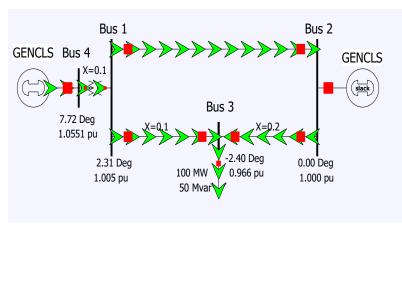

Results Comparison

• The below graph compares the angle for the generator at bus 1 using Δt =0.02 between RK2 and the Implicit Trapezoidal; also Implicit with Δt =0.06

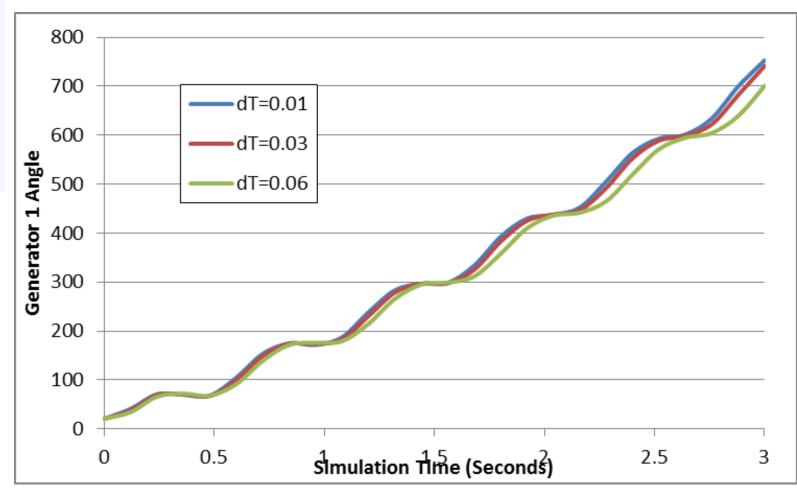

Four Bus Comparison
